## Abstract

A new species of *Sideritis* (*Sideritis carpetana*) is described from the calcareous, high-mountain Spanish flora in the central part of the Iberian Peninsula. It is found in a Mediterranean climate at high-elevation, perennial, calcareous grasslands, as well as in marble screes of anthropogenic origin in the Sierra de Guadarrama, Central System (Spain), in a reserve area within the Sierra de Guadarrama National Park, at 1996 m asl. Taxonomic morphological measurements were performed on collected specimens from Sierra de Guadarrama as well as on geographically-adjacent *Sideritis* (i.e., *S. glacialis*, *S. pungens*, *S. hyssopifolia*). The relationships among them were then explored with multivariate analysis. *Sideritis carpetana* is a dwarf shrub with an erect or decumbent habit, growing up to 15 cm; non-woody twigs with long hairs of 3–4 cells, leaves are entire, linear-oblongate, sparsely covered with trichomes; inflorescence is spiciform or slightly verticillated, flowers are yellow and nutlets ovoid. A key is supplied to help distinguish it from other high-mountain Iberian species included in section *Sideritis*. The species is unique in its combination of morphological and autoecological characters. *S. carpetana* shares similarities with *S. glacialis*, a species from Sierra Nevada, and its northern Mediterranean variant, *S. glacialis* subsp. *fontqueriana* from Sierra de Gúdar. They share morphological characters that are absent in other high-mountain *Sideritis*, reinforcing their Mediterranean character, as opposed to a more temperate or submediterranean character, such as those of the *hyssopifolia* group.

**Key words:** Calcareous high-mountain grasslands, Carpetan Mountains, high mountain species, marble outcrops, Mediterranean area, *Sideritis* sect. *Sideritis*, *Sideritis* subsect. *Fruticulosa*

## Introduction

The genus *Sideritis* L. contains 140 species found across Eurasia (Russia, Tibet, and western China), with an important centre of diversity in the Iberian Peninsula and Macaronesia. Regarding the Iberian Peninsula, there are 35 species considered in Section *Sideritis*, and 24 in Macaronesia included in Subgenus *Marrubi-*

*astrum* (Pérez de Paz and Negrín 1990; Las Heras et al. 1999; Ríos et al. 2001; Morales 2016). The number of taxa increases to 100 in one of the most comprehensive works for the genus (Obón and Rivera 1994). *Sideritis* is an interesting genus with a large number of endemics and significant variability in morphological features; but it is further complicated by the hybridization process, which occurs even between species from different sections that coincide in the same area. This variability is also associated with its broad habitat affinity on siliceous or calcareous substrate at all altitudinal levels, while consistently demonstrating a strong heliophilous character (Socorro 1982; Peris et al. 1990; Morales 2016).

On the La Flecha Pass, which connects the provinces of Madrid and Segovia, at an elevation of around 2000 m asl., we discovered a few small populations of *Sideritis* during our fieldwork in the calcareous uplands of Sierra de Guadarrama National Park that, initially appeared to be members of the *Sideritis hyssopifolia* group. An in-depth study of the plant revealed similarities with *S. glacialis*, whose closest populations are found in Sierra de Gúdar (Teruel province; ca. 400 km away). Extensive examinations led us to identify *Sideritis carpetana* as a new species in the Iberian flora, presented in this article.

## Materials and methods

### Study area and vegetation

The Central System is a mountain range running northeast-southwestern in the centre of the Iberian Peninsula. It reaches its maximum altitude at 2592 m asl in Sierra de Gredos (Almanzor peak). It divides the “Meseta”, a broad, elevated plateau with an average elevation of 670 m asl, surrounded by other mountains like Montes de León (NW) and the Cantabrian Range (N), which together define the boundary between the Temperate and Mediterranean regions. The Sistema Central comprises the following mountain ranges, from east to west: Sierra de Ayllón, Sierra de Guadarrama, Sierra de Gredos, Sierra de Gata, Peña de Francia and Sierra de Estrela.

This new species (*Sideritis carpetana*) was found in the calcareous peaks of Sierra de Guadarrama. The calcareous outcrops of Sierra de Guadarrama are located in “Collado de la Flecha” (La Flecha Pass) and the head of Artiñuelo creek, within the Sierra de Guadarrama National Park. This area is shared by the provinces of Madrid and Segovia, encompassing the two towns of Rascafría in Madrid (Mountain Public Land n. 153 “Las Calderuelas y otros”) and Trescasas in Segovia (Mountain Public Land n. 257 “La umbría de los Saltillos”). Dolomitic marble outcrops are the predominant feature among the glandular orthogneisses in these mountains. Their distribution is scattered and covers a surface of ca. 120 ha and at an altitude of ranging from 1700 to 2000 m asl (Fig. 1). Prior studies have demonstrated the fascination with this area of the Sierra de Guadarrama, which acts as a genuine “floristic island” amidst the distinctive silicicolous carpetan communities of the Central System. Although there are some notable distinctions, there is also a clear relationship with the closest high mountain limestones, the Gúdar and Javalambre mountains (Southern Iberian System; Pérez Badia et al. 1998; Gavilán et al. 2012).

Floristically, there is a set of taxa found exclusively in this locality within the Sistema Central, such as *Astragalus nevadensis* subsp. *muticus*, that grows along with another group of plants that also grow in the foothills of Sierra de

**Figure 1.** Geographical location of the study region in Spain, between the provinces of Segovia and Madrid. The marble crop status (blue square) is shown on the map. All of these mountains with summits above 1500 m asl are included in the Sierra de Guadarrama National Park.

Guadarrama (Segovia province) or in the Sierra de Pela (eastern part of Central System), such as *Arenaria erinacea*, *Seseli montanum*, *Iberis saxatilis*, *Teucrium expassum* or *Astragalus incanus* subsp. *nummularioides*. Vegetation is formed by basophilous rocky communities (found in rocky outcrops) interspersed with dry grasslands rich in chamaephytes, dominated by basophilous species with the presence of acidophilous elements.

### Morphological study

Morphological characters, measurements and detailed descriptions were conducted following the outlined by Rivera and Obón (1990), Obón and Rivera (1994), Rivera et al. (1999), using both fresh materials and dried specimens (preserved herbarium specimens). We have studied high-mountain relatives of *Sideritis* close to our study area to check morphological similarities and differences. The closest areas appear in Sierra de Gúdar and Sierra de Javalambre. We added the

Cantabrian Range as the farthest because of the Mediterranean component of its flora that relates it to the others. We did not consider the Pyrenees with a temperate climate, areas more distant the Cantabrian Range nor the Sierra Nevada, a Mediterranean mountain sharing high mountain *Sideritis* species with Sierra de Gúdar (Morales 2016). Populations from Sierra de Guadarrama were compared with specimens of high-mountain *Sideritis* species: from S. de Gúdar and S. de Javalambre, *S. glacialis* (*S. glacialis* subsp. *fontqueriana* Obón and Rivera; *S. fernandez-casasii* Rosello et al), *S. pungens* (*S. pungens* subsp. *javalambrensis*) and *Sideritis hyssopifolia* (Table 1). Due to the morphological variability in the complex of *S. hyssopifolia*, a comparison was made with the nearest subspecies in terms of distance and altitude, i.e., *S. hyssopifolia* subsp. *nocedoii* Obón and Rivera from the Cantabrian Range (Table 1). The accepted systematic arrangement of *Sideritis* follows Flora iberica (Morales 2016), but takes into account the variability reported in Obón and Rivera (1994). Additional relevant sources studied include Pau (1887); Rivas Goday and Borja (1961); Mateo and López Udías (2000); Mateo and Pisco García (2000); Peris et al. (1994); Roselló et al. (1994) and Roselló et al. (2000). Plant names follow Brummitt and Powell (1992). Acronyms of herbaria are as indicated in Index Herbariorum and its supplement (Holmgren et al. 1990; Holmgren and Holmgren 1993; Thiers (updated continuously)). A key is provided to distinguish all *Sideritis* that can reach high elevations in the Iberian mountains.

## Statistical analysis

We conducted an exploratory analysis to understand the relationships between this new species and the other high-mountain Iberian *Sideritis* species. The process was performed in two stages. The first stage consisted of examining all *Sideritis* species present in the Iberian Peninsula at medium to high altitudes that share similarities in morphological characters (Suppl. material1: table S1). Next, we compared the suspected new species to geographically-close taxa. During the first phase, we differentiated material from Sierra de Gúdar and Javalambre (both for *S. glacialis* subsp. *fontqueriana* and *S. javalambrensis*) into two forms based on altitude range: Form 1 for specimens from the highest altitude, and Form 2 for those from lower altitudes (see Fig. 2). Doing so allowed for more accurate definitions on the altitudinal criteria of the species under study. We performed an agglomerative clustering method by means of Weighted Neighbor Joining, using the Sokal-Sneath index of dissimilarity (un2) supported by 500 bootstraps for 89 morphological variables of high-mountain Iberian *Sideritis* (Rivera et al. 2014; Röhrs et al. 2023). In the second stage, we conducted an ordination method using Factor Analysis, a model of the measurement of a latent variable that cannot be directly measured with a single variable. This is a reduction technique that captures the variance in a small set of variables (Howard 2016; Tavakol and Wetzel 2020). We implemented the same dissimilarity index as in the clustering analysis.

## Results

The multivariate analysis results indicated that this species is sufficiently independent from the rest of *Sideritis* dataset (Fig. 2a, b). The dendrogram of the hierarchical clustering (Fig. 2a) displays three main groups. The first group of the dendrogram (1, Fig. 2a) includes *S. hyssopifolia* subsp. *nocedoii* from the

**Table 1.** Comparison of *Sideritis carpetana* sp. nov. with other closely-related taxa. Data on *S. glacialis*, *S. pungens* and *S. hyssopifolia* from Obon and Rivera 1994; Rivera et al. 1999; Roselló et al. 2000; Ríos et al. 2001; Morales 2016 and studied specimens. (See Suppl. material 1).

Cantabrian Range (Shn; Fig. 2a) and *S. tugiensis* from southeastern mountains of the Iberian Peninsula, Sierra de Segura (St; Fig. 2a). The second group (2, Fig. 2a) includes the new *Sideritis* from Sierra de Guadarrama (Sc; Fig. 2a) and a group of species included in *S. glacialis*. The specimens from the summits of Sierra Nevada, in the south of the Iberian Peninsula (*S. glacialis* subsp. *glacialis*, Sgg; Fig. 2a), and the two forms from Sierra de Gúdar in central eastern Spain (*S. glacialis* subsp. *fontqueriana*, Sgf1, Sgf2; Fig. 2a), which show strong similarity, suggesting they could be treated as belonging to the same subsection. A third group (3, Fig. 2a) consists of two smaller subgroups. One subgroup is from Sierra Nevada and related to *S. glacialis* but from lower altitudes

**Figure 2.** **a** hierarchical clustering (Weighed Neibor Joining) of the Iberian high-mountain *Sideritis*. The new species *Sideritis carpetana* is situated in cluster 2 with *Sideritis glacialis* gr. (Sc, *S. carpetana* sp. nov, Sgf, *S. glacialis* subsp. *fontqueriana* with two forms 1 for high-mountain areas and 2 for middle areas, Sgg, *S. glacialis* subsp. *glacialis*) **b** ordination diagram (Factorial analysis) of *Sideritis carpetana* and close taxa (Axes 1 and 2). *S. carpetana* is situated close to *Sideritis glacialis* subsp. *fontqueriana* along axis 1 but far from the other two. Axis 2 also shows the independence of *S. carpetana* from the other three species.

(oromediterranean belt) and ascribed to *S. glacialis* subsp. *vestita* (Sgve; Fig. 2a) and *S. glacialis* subsp. *virens* (Sgv; Fig. 2a). The second subgroup comprises those *Sideritis* species found in Sierra de Javalambre in the central eastern part of the Iberian Peninsula (*S. pungens* or *S. javalambrensis*, Sj1, Sj2; Fig. 2a).

Factor analysis ordination showed the separation of the new *Sideritis* species from closely related ones along axis 1 and axis 2 (Fig. 2b). The first factor analysis axis shows how Guadarrama *Sideritis* and *S. glacialis* from Sierra de Gúdar (*S. g. fontqueriana*) are separated in the negative part; while *S. h. nocedoi* from Cantabrian Range and *S. javalambrensis* (= *S. pungens*) from Sierra de Javalambre are separated in the positive part. The second axis clearly distinguishes the Guadarrama *Sideritis* from *S. javalambrensis* in the most positive part of the axis, which is also in the positive part but closer to 0; and separates *S. glacialis* from Sierra de Gúdar and *S. nocedoi* from Cantabrian Range in the negative part.

The results from the multivariate analyses clearly recognize the independence of this new *Sideritis* species from Sierra de Guadarrama. Additionally, the morphological analyses results (Table 1, Appendix 1) led to the identification of a new species from the summits of Sierra de Guadarrama that we are going to call *Sideritis carpetana* Izquierdo & Gavilán, sp. nov.; that is to be included under Sect. *Sideritis*, subsect. *Fruticulosa* due to its relationships with *Sideritis glacialis* subsp. *fontqueriana* from Sierra de Gúdar, as shown in Fig. 2a, b. The following text presents the diagnosis, holotype and other characteristics of this new species, including phenology, distribution, habitat and the detailed description with all morphological characters studied.

### ***Sideritis carpetana* Izquierdo & Gavilán, sp. nov**

urn:lsid:ipni.org:names:77355303-1

**Description (Figs 2–5).** Dwarf shrub with erect or decumbent habit, growing up to 25 cm. Stems are holotrichous with white hairs. Branchlets at the base have cylindric trichomes of 3–4 cells, except the apical band-shaped being 0.7–1.3 mm long. Leaves are entire, linear-oblongate, measuring 8–12.5 × 2.5–3.5 mm long, markedly trinerved and mucronated, sparsely covered by trichomes on the upper side of leaf and more densely covered on the underside. Middle bracts measure 6–8 mm. The inflorescence is spiciform or slightly verticillated with 5–6 whorls, each enclosing 5(6) flowers. The calyx is campanulate, densely haired, 6–8.3 mm long, teeth spiny-acuminate, equal, and erect, 2.5–3.5 long, with continuous carpostegium, spines 1–1.5 mm. The corolla is yellow 8–9 (10) mm, with entire or two slight lobes in the upper lip and three in the lower lip, the central bigger than the other two; stamens included in the corolla tube, with filaments 4–5 mm long; style 3–3.5 mm long; ovoid nutlets 1 mm (see Suppl. material1: table S1 for diagnostic features and detailed description).

This species lives in the mountains of Sierra de Guadarrama, in the marble outcrop reserve of La Flecha Pass, in the Sierra de Guadarrama National Park, on Mediterranean high-mountain calcareous grasslands and screes of anthropogenic origin, mainly in southern exposures, at an altitude of 1990–2000 m asl.

**Holotype.** • Holotype: SPAIN, Madrid: Sierra de Guadarrama. Collado de la Flecha, 1996 m asl. 14/07/2021. 40.928276, -3.925597 (ETRS89), Rosario G. Gavilán and José Luis Izquierdo, MAF [MAF 181439].

**Phenology.** The species is known to have its prime flowering season from June to July; and it is reported to fruit from August to October.

**Distribution and habitat.** *Sideritis carpetana* grows in Mediterranean high-mountain calcareous grasslands of *Festuco-Ononidetea striatae* (*Festuco carpetanae*-*Astragaletum mutici*) and in marble screes of anthropogenic origin at La Flecha Pass, Sierra de Guadarrama, at an altitude of 1996 m asl (Table 2). The geographical distribution is restricted to the marble outcrop reserve within the Sierra de Guadarrama National Park. In these territories, winter snow cover lasts for approximately five months, while summer rainfall is scarce as is typical of a Mediterranean territory.

**Table 2.** Phytosociological relevés recorded in La Flecha Pass, Association *Festuco carpetanae-Astragaletum mutici* Gavilán, Díez-Monsalve, Izquierdo, Gutiérrez- Girón, Fernández-González & Sánchez-Mata (*Sideritido-Arenarion*, *Festuco hystricis-Poetalia ligulatae*, *Festuco hystricis-Ononidetea striatae*). Species Indices and phytosociological association typology (vegetation type) follow J. Braun-Blanquet (1928).

**Etymology.** The specific epithet ‘carpetana’ refers to the former inhabitants of these mountains that were called ‘carpetanos’ (carpetan, in English). Moreover, “Cordillera Carpetana”, or Carpetan Range, is a synonym for Sistema Central (Central System), the mountain range that divides the northern and southern pla-

## Discussion

Plants living on the marble outcrops of Sierra de Guadarrama enrich the prevalent silicicolous flora of the area. The majority of these calcareous plants are found in foothill areas, but a small number of them reach altitudes above the timberline (1800–2000 m asl) and are thus included in the Sierra de Guadarrama National Park reserve. These outcrops have been identified as a floristic island surrounded by the characteristic glandular orthogneisses of these mountains (Pérez Badia et al. 1998; Gavilán et al. 2012).

According to Obón and Rivera (1994) and Rivera et al. (1999), Section *Sideritis*, subsection *Fruticulosae* includes *Sideritis* with long hairs covering the base of the branchlets (Obon and Rivera 1994); it is also holotrichous, formed by cylindrical cells, except the apical band-shaped (forming bands along the cell). This subsection consists of five species (*S. fruticulosa*, *S. spinulosa*, *S. subspinosa*, *S. jahandiezii* and *S. glacialis*), but the only species growing at high altitudes in the cryoromediterranean belt are those of the *S. glacialis* complex (subsp. *glacialis* and subsp. *fontqueriana*) or oromediterranean (subsp. *vestita* and subsp. *virens*). These species inhabit the south of the Iberian Peninsula (Sierra Nevada and surroundings mountains), with the exception of subsp. *fontqueriana*, which grows at the Sierra de Gúdar which is close to Sierra de Guadarrama, and whose specimens have been studied in the comparison with *Sideritis carpetana*.

*Sideritis* belonging to subsection *Hyssopifoliae* have shorter hairs at the base of the branchlets, goniotrichous to holotrichous, formed by cylindrical cells, and the apical cell is conical. This subsection includes 7 species (*S. brachycalix*, *S. getula*, *S. hyssopifolia*, *S. pungens*, *S. maura*, *S. carbonellii* and *S. ochroleuca*; Obon and Rivera 1994). The species found in high mountain areas are *S. carbonellii*, *S. pungens* and *S. hyssopifolia*. We have compared with *Sideritis carpetana* those found in locations close to Sierra de Guadarrama and on calcareous substrate: i.e., *S. pungens* (subsp. *javalembrensis*, Sierra de Javalambre) and *S. hyssopifolia* (subsp. *nocedoi*, Cantabrian Range). After comparing the studied characters of all the selected species in both subsections (see Table 1), we included *S. carpetana* in subsection *Fruticulosae*. This is due to the fact that it has long hairs at the base of the branchlets, which are formed by 3–4 cells (including the apical, that is band-shaped) while in the others these are conical. Like all species in this subsection, hairs in the inflorescence axis or bracts are similar to those at the base of branchlets. Morphological findings have been validated by multivariate analyses.

Similarity in macromorphological characters with other orophilous *Sideritis*, such as hair length and the type of leaves, demonstrates the ecological convergence of these species due to the harsh environmental conditions in high mountain areas and the intense speciation process (Ríos et al. 2001). This is the case for the *S. glacialis* complex, which includes four mountainous taxa, and *S. hyssopifolia*, with two subspecies with an orophilous distribution, subsp. *nocedoi* from the Cantabrian Range and subsp. *eynensis* from eastern Pyrenees. Although Sierra de Guadarrama is sometimes thought of as submediterranean due to a slightly shorter summer arid season compared to southern territories like Sierra Nevada, it shares similarities in ecology, distribution, and characters with the Sierra de Gúdar *Sideritis* (*S. glacialis*, *S. glacialis* subsp. *fontqueriana*). This is evident in *S. carpetana* which has long trichomes at the base of non-woody twigs and other parts, as well as the holotrichous indumen-

tum, which is similar to taxa found in Mediterranean zones. This marked Mediterranean character of Sierra de Guadarrama and its relationships with Sierra Nevada vegetation has been highlighted in recent revisions of high Iberian vegetation (Gavilán et al. 2017). On the other hand, the rhizomatous habit is also a typical characteristic of orophilous taxa, for instance *S. lurida* (subsect. *Lurida*), found close to the Sierra de Gredos (Central System), grows in loose substrates (scree) similar to *S. carpetana*, although these are of geological origin and not anthropogenic, as in our case (Rivera and Obón 1990; Luceño et al. 2000).

A comprehensive flora checklist for the siliceous substrate, which is more prevalent along the Central System exists (Rivas-Martínez 1963; Sánchez-Mata 1988, Fernández-González 1988; Luceño et al. 2000), while the scarce and dispersed calcareous areas, which have a particular flora, have received less attention. However, there have been recent discoveries of new plant species in those well-known areas, such as the Sierra de Guadarrama (Fernández-González and Izco 1989). In the uplands of La Flecha Pass, the marble outcrops are interspersed with the typical preponderance of orthogneisses that conceal the calcareous landscape. Their preservation is currently a top priority in the Sierra de Guadarrama National Park. It has applied conservation measures to this natural reserve, as outlined in the Spanish National Parks Law 30/2014, which include several uses that are incompatible with the current management practices, such as public usage (visits) and substantial animal grazing (livestock). The area is currently described as having high ecological significance and unique natural assets that are of exceptional rarity, fragility, and scientific interest in order to ensure proper protection for these marble outcrops.

## Additional information

### Conflict of interest

The authors have declared that no competing interests exist.

### Ethical statement

No ethical statement was reported.

### Funding

This work was supported by Universidad Complutense de Madrid. Project number PR3/23-30823.

### Author contributions

JLI and RGG: conceived the paper; JLI, RMU, AGG, RGG: sampling in Sierra de Guadarrama; COC, DR, RGG: analyzed data by multivariate analyses and wrote the corresponding texts. RGG compiled the first versions of the text; All authors contributed to the writing in the last version; RMU: correct the English.

## Appendix 1

Specimens studied.

### ***Sideritis glacialis* (incl. subsp. *fontqueriana*, *S. fernandez-casasii*)**

TERUEL: Puerto de Valdelinares, 30TYX07, 1800 m asl, in Junipero sabinae-Pinetum sylvestris. *Andrés Molina*, 5-8-1982, MAF 120116; Altos de la Sierra de Gúdar. *Salvador Rivas Goday*, 24-6-1946, MAF 77086; 4-7-1995, Valdelinares, Sierra de Gúdar, estación invernal, *Vicente Jesús Arán*, MA561273; Valdelinares, próximo a la desviación de Peñaroya, 29-08-2002, *J. Herrero*, MA700968; Cerca de la Virgen de la Vega, Alcalá de la Selva, Collado de la Gitana, 10-7-1946, *Font Quer, Sierra y Torres*, MA344902; Sierra de Gúdar, 1900 m, 5-8-1974, *G. López & E. Valdés-Bermejo*, MA435326.

GRANADA: Sierra Nevada, 24-8-1977, *E. Rico*, MA 212210; Capileira, Sierra Nevada, Vasares del Veleta, laderas rocosas y pedregosas, micaesquistos, 3020 m asl, 19-8-1990, *L.F. Sánchez & J.A. Alejandro*, MA 493728

### ***Sideritis hyssopifolia* (incl. subsp. *nocadoi*)**

LEÓN: Boca de Huérgano, macizo de Peña Prieta, roquedos calizos en laders de solana del valle de Lechada, 1970-2060 m asl, 16-7-1990, *M.L. Gil Zúñiga & J.A. Alejandro*, MA493729; San Emiliano, Peña Ubiña, SE, laderas pedregosas calcáreas, 30TTN5967, 2000 m, 30-7-2001, *V.J. Arán & M.J. Tohá*, MA691953; Circo Cebollero, Puerto de San Isidro, 27-7-1979, *Casaseca, Fernández, Amich, Rico & Sánchez*, MA256354; Between Nocado and Valdeteja, 1800 masl, 27-8-1972, *Salvador Rivas Goday and Jesús Izco*. MA256357, *ibidem* MAF84289.

### ***Sideritis pungens* (incl. subsp. *javalambrensis*, *S. javalambrensis*)**

TERUEL: Camarena de la Sierra, Javalambre peak, 30TXK6841, 2000 m asl, in lapidosis calcareis, 18-9-1981, leg. *Santiago Castroviejo, Fernández Quirós*, det. *José Borja*. MAF 127937; *ibidem* MA381171; La Puebla de Valverde, cerro de Javalambre, junto a las instalaciones de televisión, 7-7-1995, *Vicente Jesús Arán*, MA561283; Sierra de Javalambre, 2000 m, 11-9-1900, *F. Sennen*, MA100605; Pico Javalambre, matorrales pulvinulares de Erodio-Erinacetum, 1-7-1983, *Peris, Stubing & González*, MA479758.

## Supplementary material 1

### Supplementary information

Authors: Jose Luis Izquierdo, Rosina Magaña Ugarte, Alba Gutiérrez-Girón, Concepción Obón de Castro, Diego Rivera Núñez , Rosario G. Gavilán

Data type: pdf

Explanation note: Detailed description on *Sideritis carpetana*. **table S1**. Data on taxa included in the multivariate analysis done to the Iberian *Sideritis* from high and medium altitudes. **table S2**. Comparison of *Sideritis carpetana* sp. nov. with other closely-related taxa.
